

Forecasting: principles and practice

Rob J Hyndman

3.1 Dynamic regression

Outline

- 1 Regression with ARIMA errors
- 2 Lab session 18
- 3 Some useful predictors for linear models
- 4 Dynamic harmonic regression
- 5 Lab session 19
- **6** Lagged predictors

Regression models

$$y_t = \beta_0 + \beta_1 x_{1,t} + \cdots + \beta_k x_{k,t} + \varepsilon_t,$$

- y_t modeled as function of k explanatory variables $x_{1,t}, \ldots, x_{k,t}$.
- In regression, we assume that ε_t was WN.
- Now we want to allow ε_t to be autocorrelated.

Regression models

$$y_t = \beta_0 + \beta_1 x_{1,t} + \cdots + \beta_k x_{k,t} + \varepsilon_t,$$

- y_t modeled as function of k explanatory variables $x_{1,t}, \ldots, x_{k,t}$.
- In regression, we assume that ε_t was WN.
- Now we want to allow ε_t to be autocorrelated.

Example: ARIMA(1,1,1) errors

$$y_{t} = \beta_{0} + \beta_{1} x_{1,t} + \dots + \beta_{k} x_{k,t} + \eta_{t},$$

$$(1 - \phi_{1} B)(1 - B)\eta_{t} = (1 + \theta_{1} B)\varepsilon_{t},$$

where ε_t is white noise.

Residuals and errors

Example: η_t = ARIMA(1,1,1)

$$y_t = \beta_0 + \beta_1 x_{1,t} + \dots + \beta_k x_{k,t} + \eta_t,$$

 $(1 - \phi_1 B)(1 - B)\eta_t = (1 + \theta_1 B)\varepsilon_t,$

Residuals and errors

Example: η_t = ARIMA(1,1,1)

$$y_t = \beta_0 + \beta_1 x_{1,t} + \dots + \beta_k x_{k,t} + \eta_t,$$

 $(1 - \phi_1 B)(1 - B)\eta_t = (1 + \theta_1 B)\varepsilon_t,$

- Be careful in distinguishing η_t from ε_t .
- Only the errors η_t are assumed to be white noise.
- In ordinary regression, η_t is assumed to be white noise and so $\eta_t = \varepsilon_t$.

4

Estimation

If we minimize $\sum \eta_t^2$ (by using ordinary regression):

- Estimated coefficients $\hat{\beta}_0, \dots, \hat{\beta}_k$ are no longer optimal as some information ignored;
- 2 Statistical tests associated with the model (e.g., t-tests on the coefficients) are incorrect.
- *p*-values for coefficients usually too small ("spurious regression").
- 4 AIC of fitted models misleading.

Estimation

If we minimize $\sum \eta_t^2$ (by using ordinary regression):

- Estimated coefficients $\hat{\beta}_0, \dots, \hat{\beta}_k$ are no longer optimal as some information ignored;
- Statistical tests associated with the model (e.g., t-tests on the coefficients) are incorrect.
- *p*-values for coefficients usually too small ("spurious regression").
- 4 AIC of fitted models misleading.
 - Minimizing $\sum \varepsilon_t^2$ avoids these problems.
 - Maximizing likelihood is similar to minimizing $\sum \varepsilon_t^2$.

Stationarity

Regression with ARMA errors

$$y_t = \beta_0 + \beta_1 x_{1,t} + \cdots + \beta_k x_{k,t} + \eta_t,$$
 where η_t is an ARMA process.

- If we estimate the model while any variable is non-stationary, the estimated coefficients can be incorrect.
- Difference variables until all stationary.
- If necessary, apply same differencing to all variables to preserve interpretability.

Any regression with an ARIMA error can be rewritten as a regression with an ARMA error by differencing all variables with the same differencing operator as in the ARIMA model.

Any regression with an ARIMA error can be rewritten as a regression with an ARMA error by differencing all variables with the same differencing operator as in the ARIMA model.

Original data

$$\begin{aligned} \mathbf{y}_t &= \beta_0 + \beta_1 \mathbf{x}_{1,t} + \dots + \beta_k \mathbf{x}_{k,t} + \eta_t \\ \text{where} \quad \phi(\mathbf{B}) (1 - \mathbf{B})^d \eta_t &= \theta(\mathbf{B}) \varepsilon_t \end{aligned}$$

Any regression with an ARIMA error can be rewritten as a regression with an ARMA error by differencing all variables with the same differencing operator as in the ARIMA model.

Original data

$$\begin{aligned} \mathbf{y}_t &= \beta_0 + \beta_1 \mathbf{x}_{1,t} + \dots + \beta_k \mathbf{x}_{k,t} + \eta_t \\ \text{where} \quad \phi(\mathbf{B}) (1-\mathbf{B})^d \eta_t &= \theta(\mathbf{B}) \varepsilon_t \end{aligned}$$

After differencing all variables

$$\begin{aligned} \mathbf{y}_t' &= \beta_1 \mathbf{x}_{1,t}' + \dots + \beta_k \mathbf{x}_{k,t}' + \eta_t'. \\ \text{where} \quad \phi(\mathbf{B}) \eta_t &= \theta(\mathbf{B}) \varepsilon_t \\ \text{and} \quad \mathbf{y}_t' &= (\mathbf{1} - \mathbf{B})^d \mathbf{y}_t \end{aligned}$$

Model selection

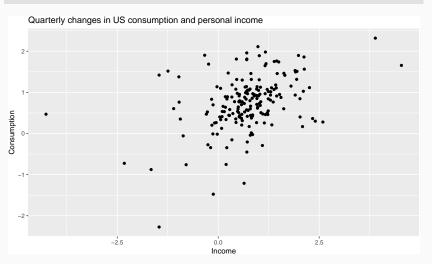

- Fit regression model with automatically selected ARIMA errors.
- Check that ε_t series looks like white noise.

Selecting predictors

- AICc can be calculated for final model.
- Repeat procedure for all subsets of predictors to be considered, and select model with lowest AICc value.

```
autoplot(uschange[,1:2], facets=TRUE) +
  xlab("Year") + ylab("") +
  ggtitle("Quarterly changes in US consumption and personal income")
   Quarterly changes in US consumption and personal income
 -1 -
 -2-
-2.5 -
     1970
                   1980
                                                 2000
                                                               2010
```

```
qplot(Income,Consumption, data=as.data.frame(uschange)) +
   ggtitle("Quarterly changes in US consumption and personal income")
```

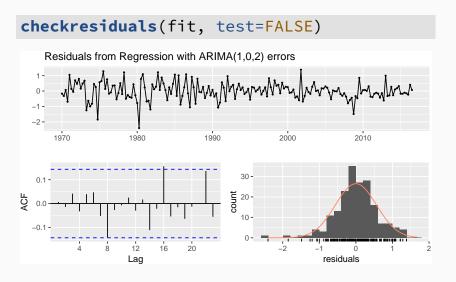

- No need for transformations or further differencing.
- Increase in income does not necessarily translate into instant increase in consumption (e.g., after the loss of a job, it may take a few months for expenses to be reduced to allow for the new circumstances). We will ignore this for now.

```

Forecasting

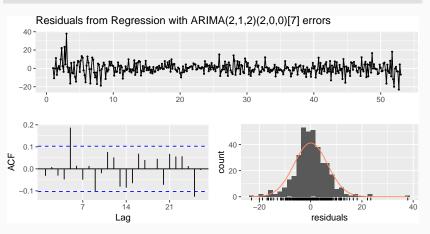

- To forecast a regression model with ARIMA errors, we need to forecast the regression part of the model and the ARIMA part of the model and combine the results.
- Some predictors are known into the future (e.g., time, dummies).
- Separate forecasting models may be needed for other predictors.
- Forecast intervals ignore the uncertainty in forecasting the predictors.

Model daily electricity demand as a function of temperature using quadratic regression with ARMA errors.

Lab Session 18

Outline

- 1 Regression with ARIMA errors
- 2 Lab session 18
- 3 Some useful predictors for linear models
- 4 Dynamic harmonic regression
- 5 Lab session 19
- **6** Lagged predictors

Trend

Linear trend

$$x_t = t$$

- t = 1, 2, ..., T
- Strong assumption that trend will continue.

Dummy variables

If a categorical variable takes only two values (e.g., 'Yes' or 'No'), then an equivalent numerical variable can be constructed taking value 1 if yes and 0 if no. This is called a dummy variable.

	A	В
1	Yes	
2	Yes	
3	No	
4	Yes	
5	No	
6	No	
7	Yes	
8	Yes	
9	No	
10	No	
11	No	
12	No	
13	Yes	
14	No	

Dummy variables

If there are more than two categories, then the variable can be coded using several dummy variables (one fewer than the total number of categories).

		Α	В	С	D	Е
,	1	Monday	1	0	0	0
	2	Tuesday	0	1	0	0
	3	Wednesday	0	0	1	0
	4	Thursday	0	0	0	1
	5	Friday	0	0	0	0
	6	Monday	1	0	0	0
	7	Tuesday	0	1	0	0
	8	Wednesday	0	0	1	0
	9	Thursday	0	0	0	1
	10	Friday	0	0	0	0
	11	Monday	1	0	0	0
	12	Tuesday	0	1	0	0
	13	Wednesday	0	0	1	0
	14	Thursday	0	0	0	1
	15	Friday	0	0	0	0

Beware of the dummy variable trap!

- Using one dummy for each category gives too many dummy variables!
- The regression will then be singular and inestimable.
- Either omit the constant, or omit the dummy for one category.
- The coefficients of the dummies are relative to the omitted category.

Uses of dummy variables

Seasonal dummies

- For quarterly data: use 3 dummies
- For monthly data: use 11 dummies
- For daily data: use 6 dummies
- What to do with weekly data?

Uses of dummy variables

Seasonal dummies

- For quarterly data: use 3 dummies
- For monthly data: use 11 dummies
- For daily data: use 6 dummies
- What to do with weekly data?

Outliers

If there is an outlier, you can use a dummy variable (taking value 1 for that observation and 0 elsewhere) to remove its effect.

Uses of dummy variables

Seasonal dummies

- For quarterly data: use 3 dummies
- For monthly data: use 11 dummies
- For daily data: use 6 dummies
- What to do with weekly data?

Outliers

If there is an outlier, you can use a dummy variable (taking value 1 for that observation and 0 elsewhere) to remove its effect.

Public holidays

■ For daily data: if it is a public holiday, dummy=1, otherwise dummy=0.

Fourier series

Periodic seasonality can be handled using pairs of Fourier terms:

$$s_k(t) = \sin\left(\frac{2\pi kt}{m}\right) \qquad c_k(t) = \cos\left(\frac{2\pi kt}{m}\right)$$
$$y_t = a + bt + \sum_{k=1}^{K} \left[\alpha_k s_k(t) + \beta_k c_k(t)\right] + \varepsilon_t$$

- Every periodic function can be approximated by sums of sin and cos terms for large enough K.
- Choose K by minimizing AICc.
- Called "harmonic regression"
- fourier() function generates these.

Intervention variables

Spikes

Equivalent to a dummy variable for handling an outlier.

Intervention variables

Spikes

Equivalent to a dummy variable for handling an outlier.

Steps

Variable takes value 0 before the intervention and 1 afterwards.

Intervention variables

Spikes

Equivalent to a dummy variable for handling an outlier.

Steps

Variable takes value 0 before the intervention and 1 afterwards.

Change of slope

■ Variables take values 0 before the intervention and values $\{1, 2, 3, \dots\}$ afterwards.

Holidays

For monthly data

- Christmas: always in December so part of monthly seasonal effect
- Easter: use a dummy variable $v_t = 1$ if any part of Easter is in that month, $v_t = 0$ otherwise.
- Ramadan and Chinese new year similar.

Trading days

With monthly data, if the observations vary depending on how many different types of days in the month, then trading day predictors can be useful.

```
z<sub>1</sub> = # Mondays in month;
z<sub>2</sub> = # Tuesdays in month;
:
z<sub>7</sub> = # Sundays in month.
```

Distributed lags

Lagged values of a predictor.

Example: x is advertising which has a delayed effect

```
    x<sub>1</sub> = advertising for previous month;
    x<sub>2</sub> = advertising for two months previously;
    :
    x<sub>m</sub> = advertising for m months previously.
```

Outline

- 1 Regression with ARIMA errors
- 2 Lab session 18
- 3 Some useful predictors for linear models
- 4 Dynamic harmonic regression
- 5 Lab session 19
- **6** Lagged predictors

Dynamic harmonic regression

Combine Fourier terms with ARIMA errors

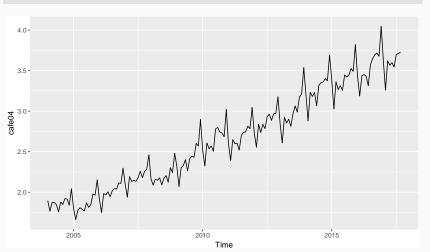

Advantages

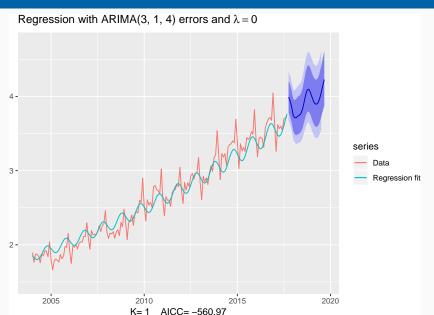

- it allows any length seasonality;
- for data with more than one seasonal period, you can include Fourier terms of different frequencies;
- the seasonal pattern is smooth for small values of K (but more wiggly seasonality can be handled by increasing K);
- the short-term dynamics are easily handled with a simple ARMA error.

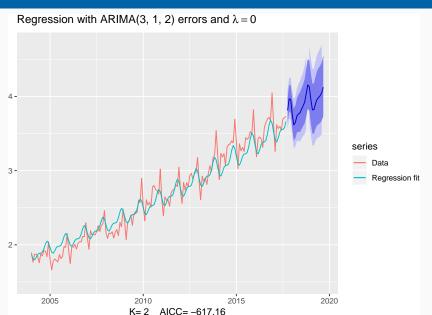

Disadvantages

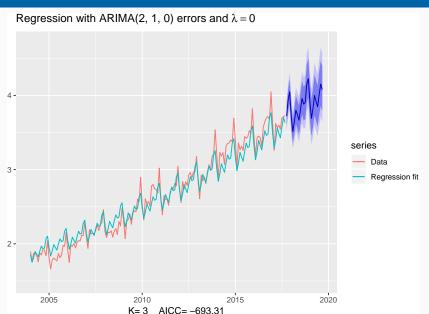

seasonality is assumed to be fixed

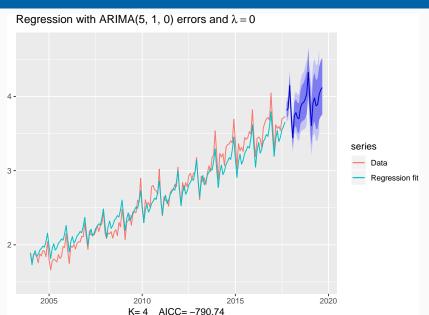

```
cafe04 <- window(auscafe, start=2004)
autoplot(cafe04)</pre>
```

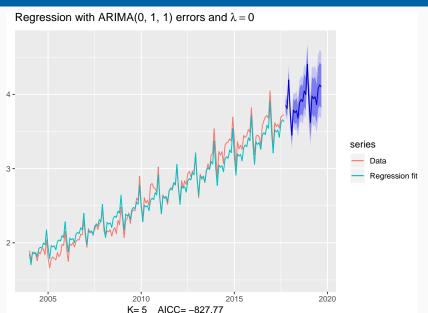

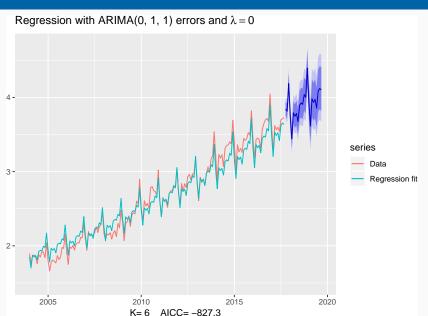

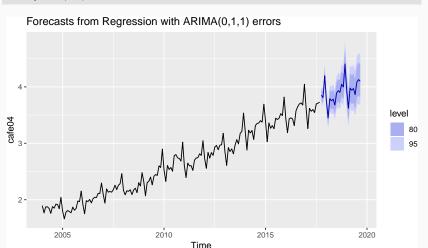

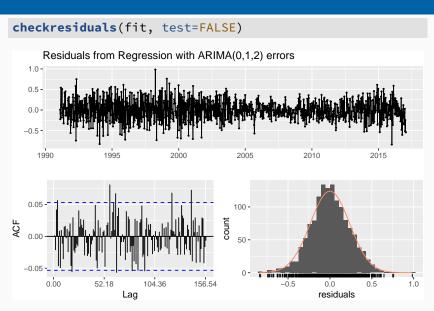

harmonics <- fourier(gasoline, K = 13)

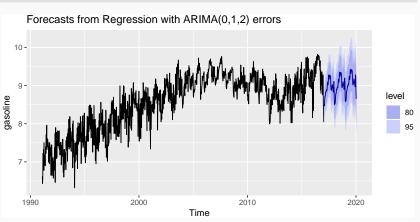

```
(fit <- auto.arima(gasoline, xreg = harmonics, seasonal = FALSE))

Lab Session 19

Outline

- 1 Regression with ARIMA errors
- 2 Lab session 18
- 3 Some useful predictors for linear models
- 4 Dynamic harmonic regression
- 5 Lab session 19
- **6** Lagged predictors

Sometimes a change in x_t does not affect y_t instantaneously

Sometimes a change in x_t does not affect y_t instantaneously

- y_t = sales, x_t = advertising.
- y_t = stream flow, x_t = rainfall.
- y_t = size of herd, x_t = breeding stock.

Sometimes a change in x_t does not affect y_t instantaneously

- y_t = sales, x_t = advertising.
- y_t = stream flow, x_t = rainfall.
- y_t = size of herd, x_t = breeding stock.
- These are dynamic systems with input (x_t) and output (y_t) .
- \blacksquare x_t is often a leading indicator.
- There can be multiple predictors.

The model include present and past values of predictor: $x_t, x_{t-1}, x_{t-2}, \ldots$

$$y_t = a + \nu_0 x_t + \nu_1 x_{t-1} + \dots + \nu_k x_{t-k} + \eta_t$$

where η_t is an ARIMA process.

The model include present and past values of predictor: $x_t, x_{t-1}, x_{t-2}, \ldots$

$$y_t = a + \nu_0 x_t + \nu_1 x_{t-1} + \cdots + \nu_k x_{t-k} + \eta_t$$

where η_t is an ARIMA process.

Rewrite model as

$$y_t = a + (\nu_0 + \nu_1 B + \nu_2 B^2 + \dots + \nu_k B^k) x_t + \eta_t$$

= $a + \nu(B) x_t + \eta_t$.

The model include present and past values of predictor: $x_t, x_{t-1}, x_{t-2}, \ldots$

$$y_t = a + \nu_0 x_t + \nu_1 x_{t-1} + \dots + \nu_k x_{t-k} + \eta_t$$

where η_t is an ARIMA process.

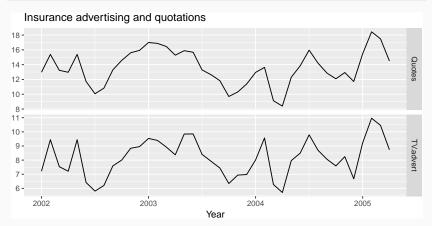

Rewrite model as

$$y_t = a + (\nu_0 + \nu_1 B + \nu_2 B^2 + \dots + \nu_k B^k) x_t + \eta_t$$

= $a + \nu(B) x_t + \eta_t$.

- ν (B) is called a *transfer function* since it describes how change in x_t is transferred to y_t .
- x can influence y, but y is not allowed to influence x.

```
